Project Overview

This is Sky E on AI note taker. How it works is that the device will record and then the device has a built in speech to text software with also MP3 log. How you do it is you first record yourself Talking someone speaking or anything along the lines of that then an AI will go over it see where there were

distinctions see what was the important message and transcribe it down, for example if you're listening to a lecture it might take notes for you but if you wanted it to judge your own speaking it might tell you where you said um or ah. There's also a built-in XP Task mode. How that works is pretty simple: you talk to it, it'll split them up into tasks, give them certain "XP levels" and then use that to figure out how important each task is. These features make it the perfect tool to have in a classroom or just when you're talking to yourself or practicing for speech as it can find the key ideas and analyze your speaking patterns and find redundancies. On top of that it is all on a miniature device with a Raspberry Pi 5 that can export on all features there's a button where you can export your conversation or

notes to a notepad drive into your flash drive this is super useful for if you wanted to "take a conversation with you in a way". This project was pretty challenging as although a solid amount of code was vibe coded. I made sure that I understood everything and manually debugged it when there were errors. On top of that I had to learn a lot more about command prompt to do this on the PI. All of this was done in the allotted time window from setting up and flashing the Raspberry Pi 5 to 3D printing and cadding the shell.
